## Introduction

Figure 1: Role of carbonic anhydrase in C<sub>4</sub> photosynthesis.

- C<sub>4</sub> photosynthesis concentrates CO<sub>2</sub> around Rubisco by biochemically shuttling four-carbon acids to bundle sheath cells. Atmospheric CO<sub>2</sub> enters the leaf airspace and diffuses into the mesophyll cells where it is substrate for carbonic anhydrase (CA)
- CA rapidly catalyzes the formation of HCO<sub>3</sub><sup>-</sup> which is subsequently fixed by PEP carboxylase (PEPC)
- At ambient [CO<sub>2</sub>] and 25°C a maize double knockdown mutant of the two mesophyll CA genes (*ca1ca2*) did not limit photosynthesis despite *ca1ca2* plants having 3% of wild-type CA activity (Studer et al., 2014).
- The role of CA in the conductivity of CO<sub>2</sub> movement into mesophyll cells (mesophyll conductance—g<sub>m</sub>) in C<sub>4</sub> plants is unknown.
- Methods to measure g<sub>m</sub> in C<sub>4</sub> plants are influenced by CA. Therefore, the *ca1ca2* mutants provide the unique opportunity to evaluate the sensitivity of g<sub>m</sub> methods.

## Objectives

1. Determine if CA limits photosynthesis at elevated temperatures during C<sub>4</sub> photosynthesis
2. Quantify the contribution of CA to substrate availability for C<sub>4</sub> photosynthesis
3. Determine the role of CA in C<sub>4</sub> mesophyll CO<sub>2</sub> conductance

## Materials and Methods

- Wild-type and *ca1ca2* plants were grown under elevated CO<sub>2</sub> (1%), 500 μmol m<sup>-2</sup> s<sup>-1</sup> PPFD, 16 hr days, and 31/28°C day/night regime
- Assimilation vs intercellular CO<sub>2</sub> (A/C<sub>i</sub>) curves were measured on *ca1ca2* and wild-type maize plants from 10 to 40°C at 5°C increments
- Biochemical assays of Rubisco, PEPC, and CA activity were measured *in vitro* on crude leaf extract
- A/C<sub>i</sub> curves at 15, 25, and 35°C were coupled with on-line measurements of Δ<sup>13</sup>CO<sub>2</sub>, Δ<sup>18</sup>CO<sub>2</sub> and δ<sup>18</sup>O of transpired water

## Results

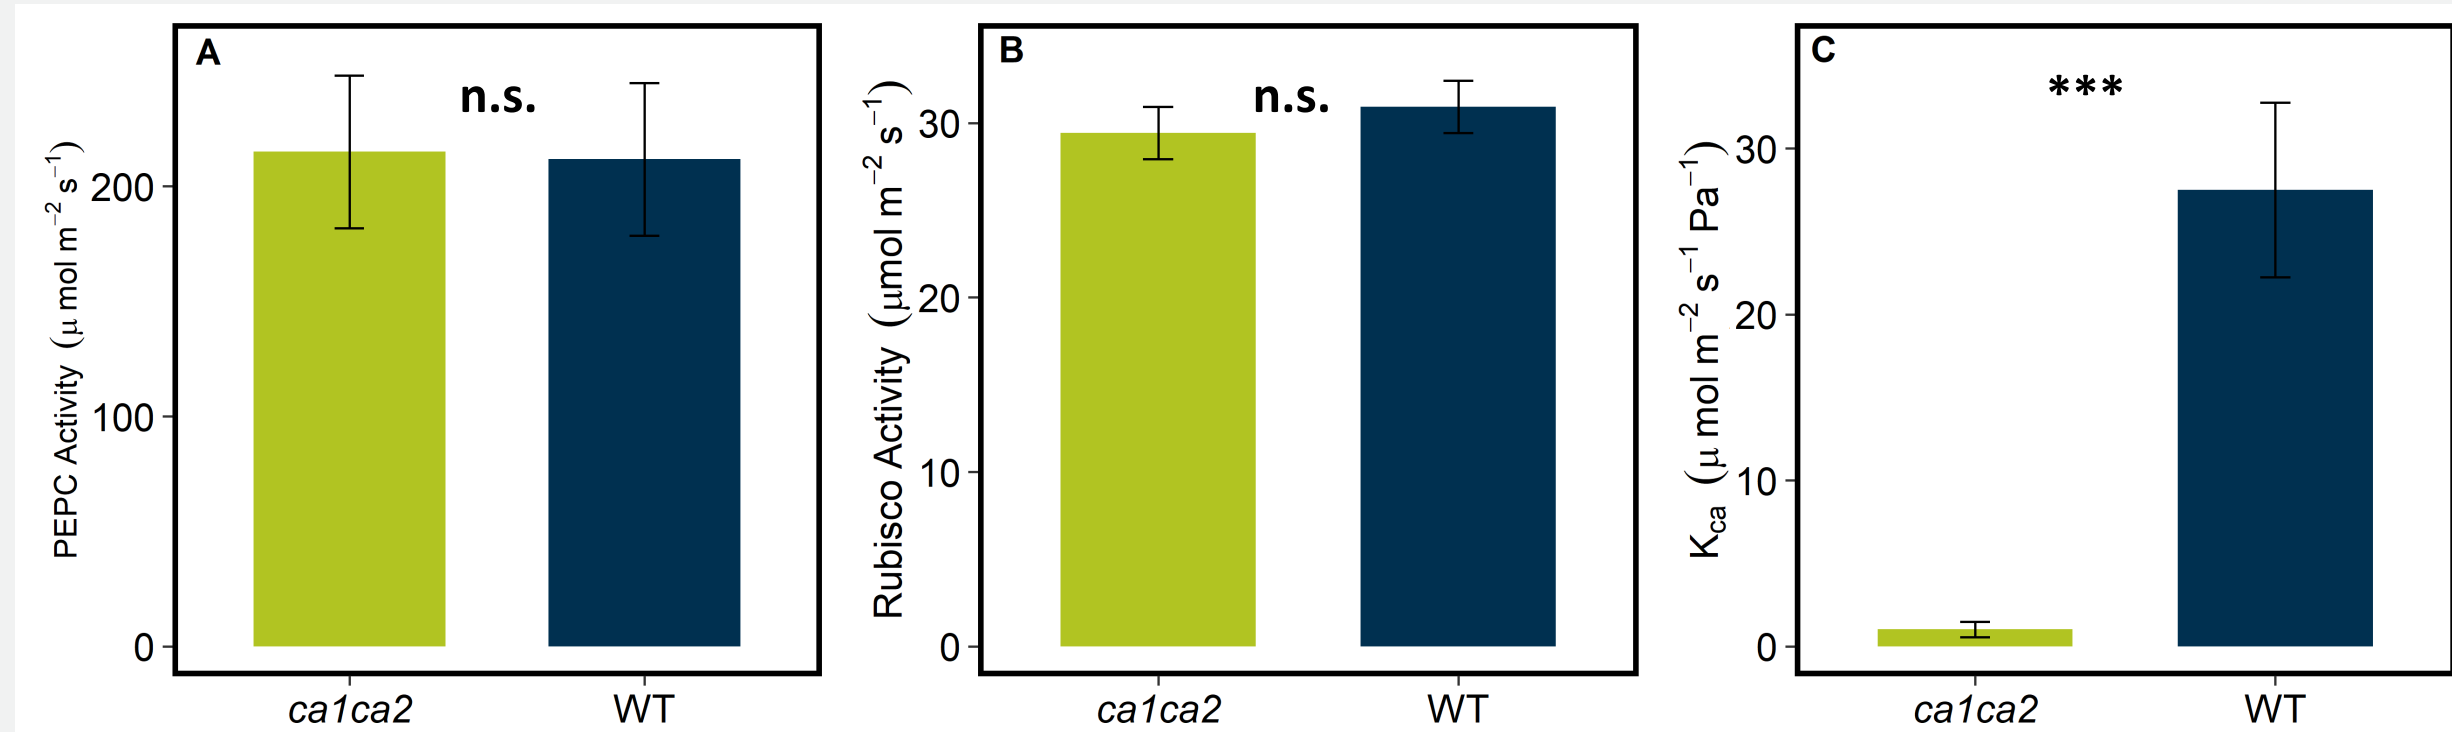

Figure 2: Mean *in vitro* enzyme activity for *ca1ca2* and WT plants (n=8) for A) PEPC, B) Rubisco, and C) the rate constant for carbonic anhydrase at 25°C. \*\*\* statistically significant difference from t-tests at alpha = 0.05.

- *ca1ca2* disruptions only reduced CA activity

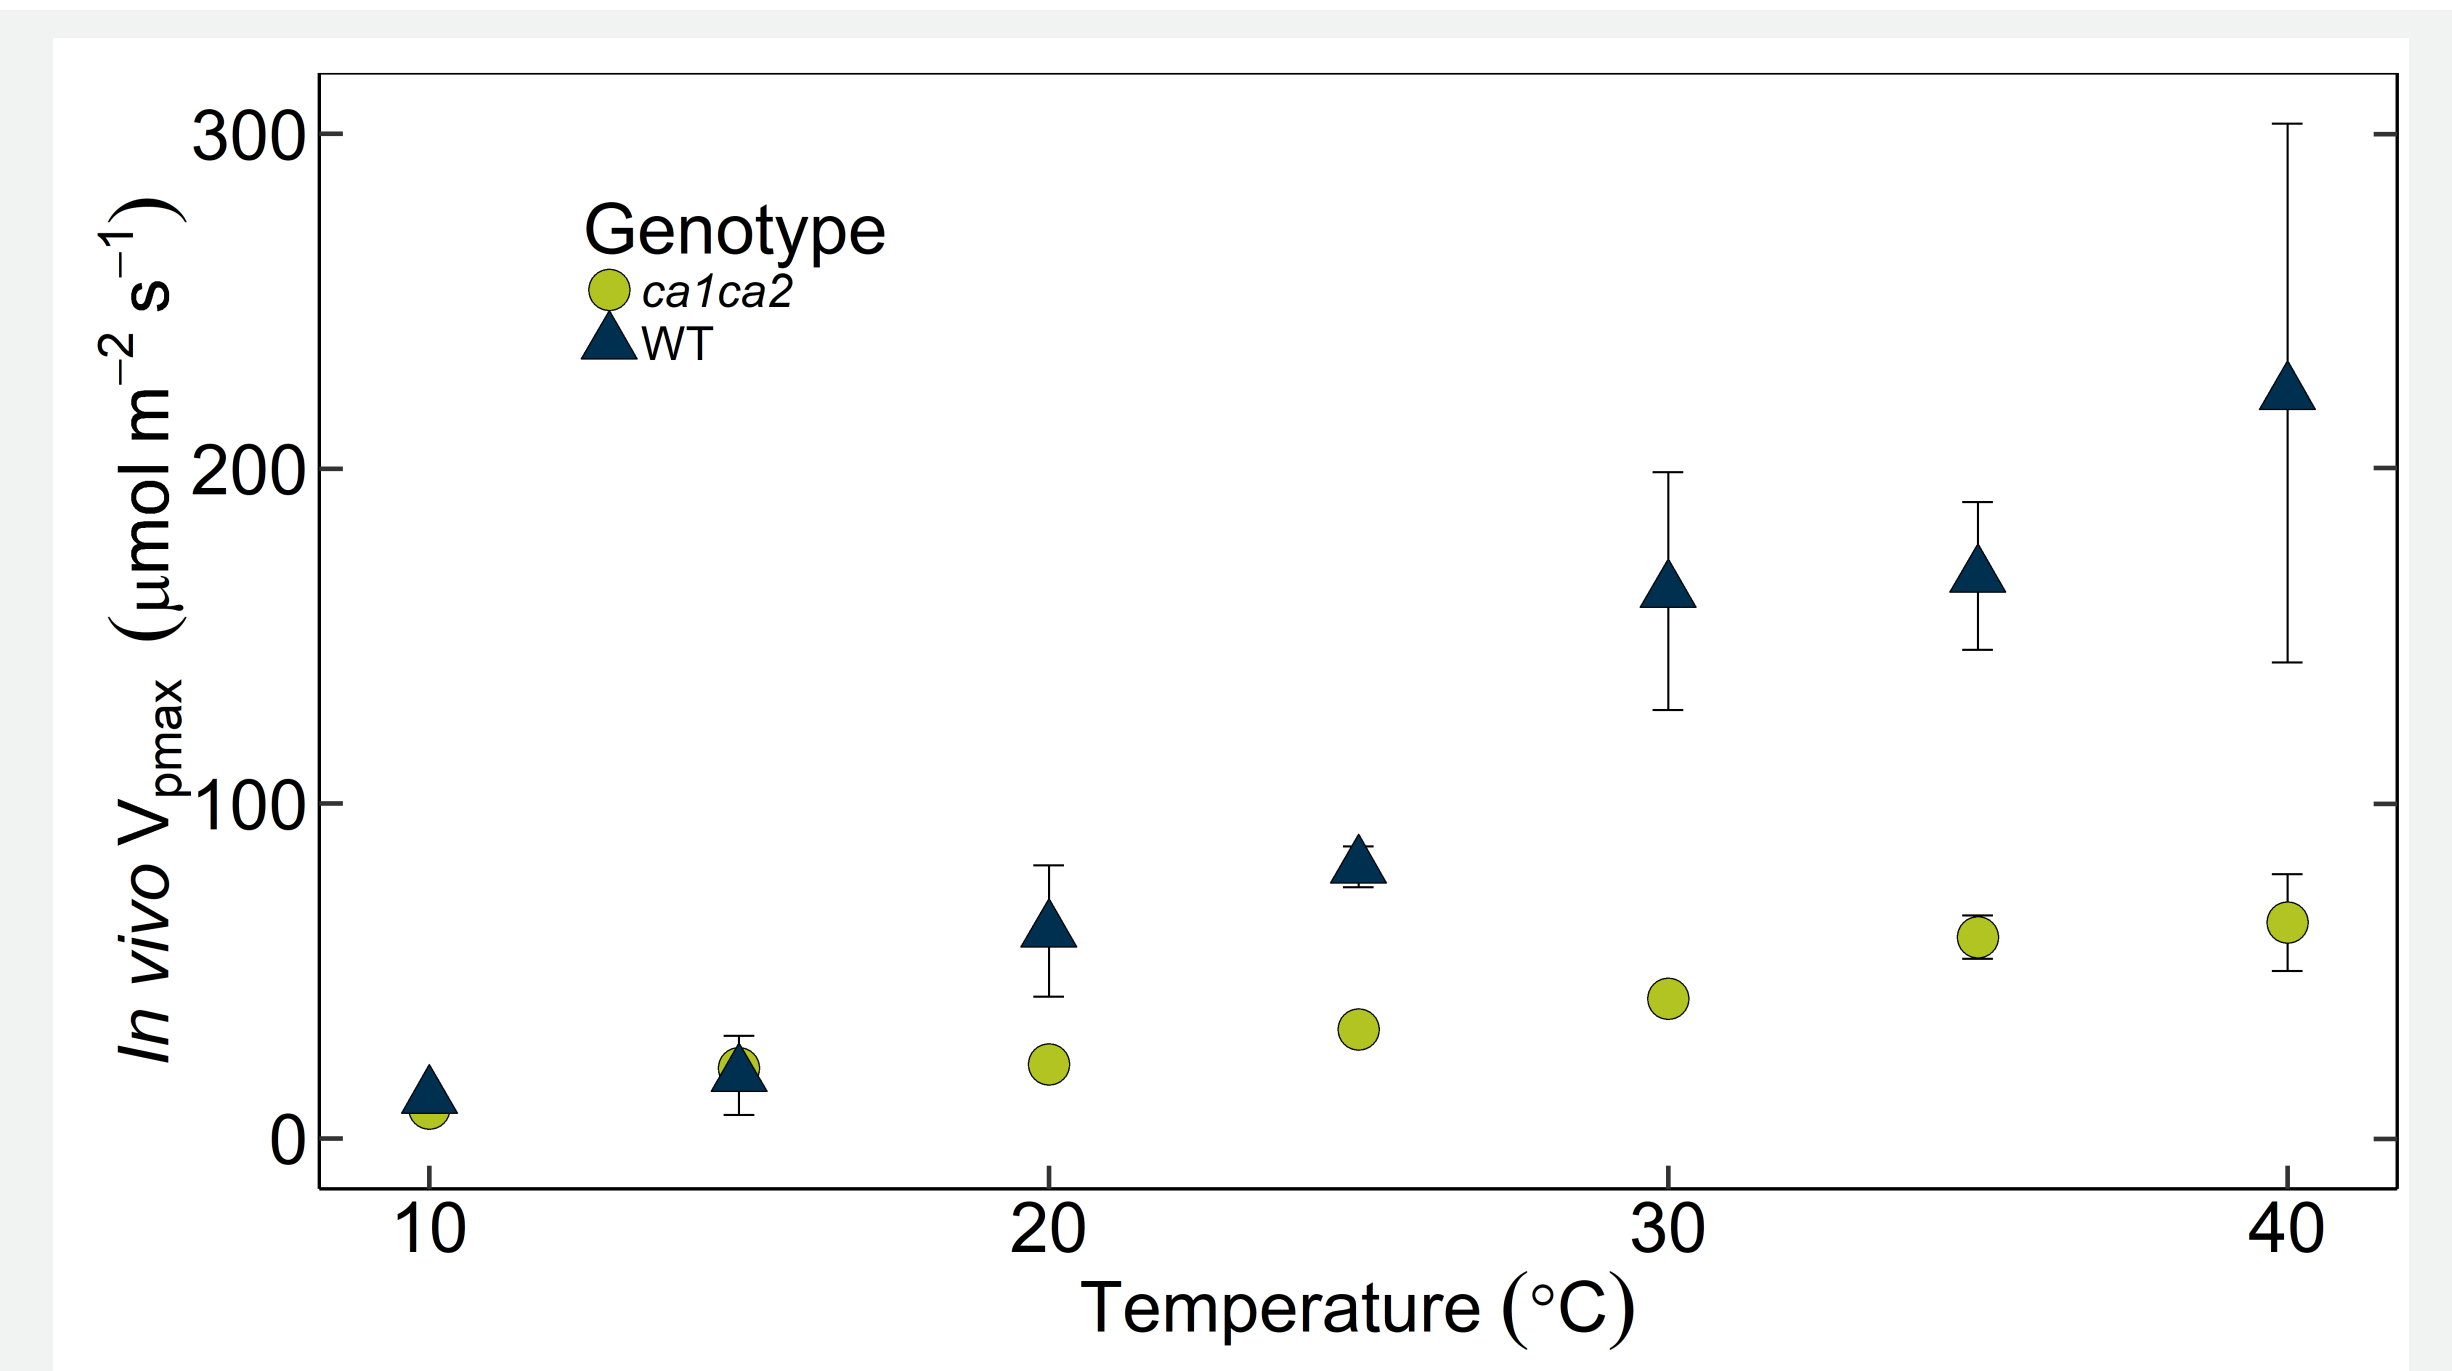

Figure 3: *ca1ca2* and WT *in vivo* V<sub>pmax</sub> calculated from 10 to 40°C by solving for the initial slope of A/C<sub>i</sub> curves modeled with the temperature responses of C<sub>4</sub> photosynthetic parameters from Boyd et al., 2015. Infinite g<sub>m</sub> assumed. n= 4

- Suggests PEPC limitation at higher temperatures in *ca1ca2* plants
- Differences could be attributed to CO<sub>2</sub>, HCO<sub>3</sub><sup>-</sup>, or PEPC

Figure 4: Gas exchange measurements vs C<sub>i</sub> curves for *ca1ca2* and WT at 15, 25, and 35°C. A) Net CO<sub>2</sub> assimilation rate, B) stomatal conductance, and C) transpiration efficiency calculated as net CO<sub>2</sub> assimilation/stomatal conductance.

- CA mutants lose more water per CO<sub>2</sub> fixed because of reduced assimilation rate, not stomatal conductance

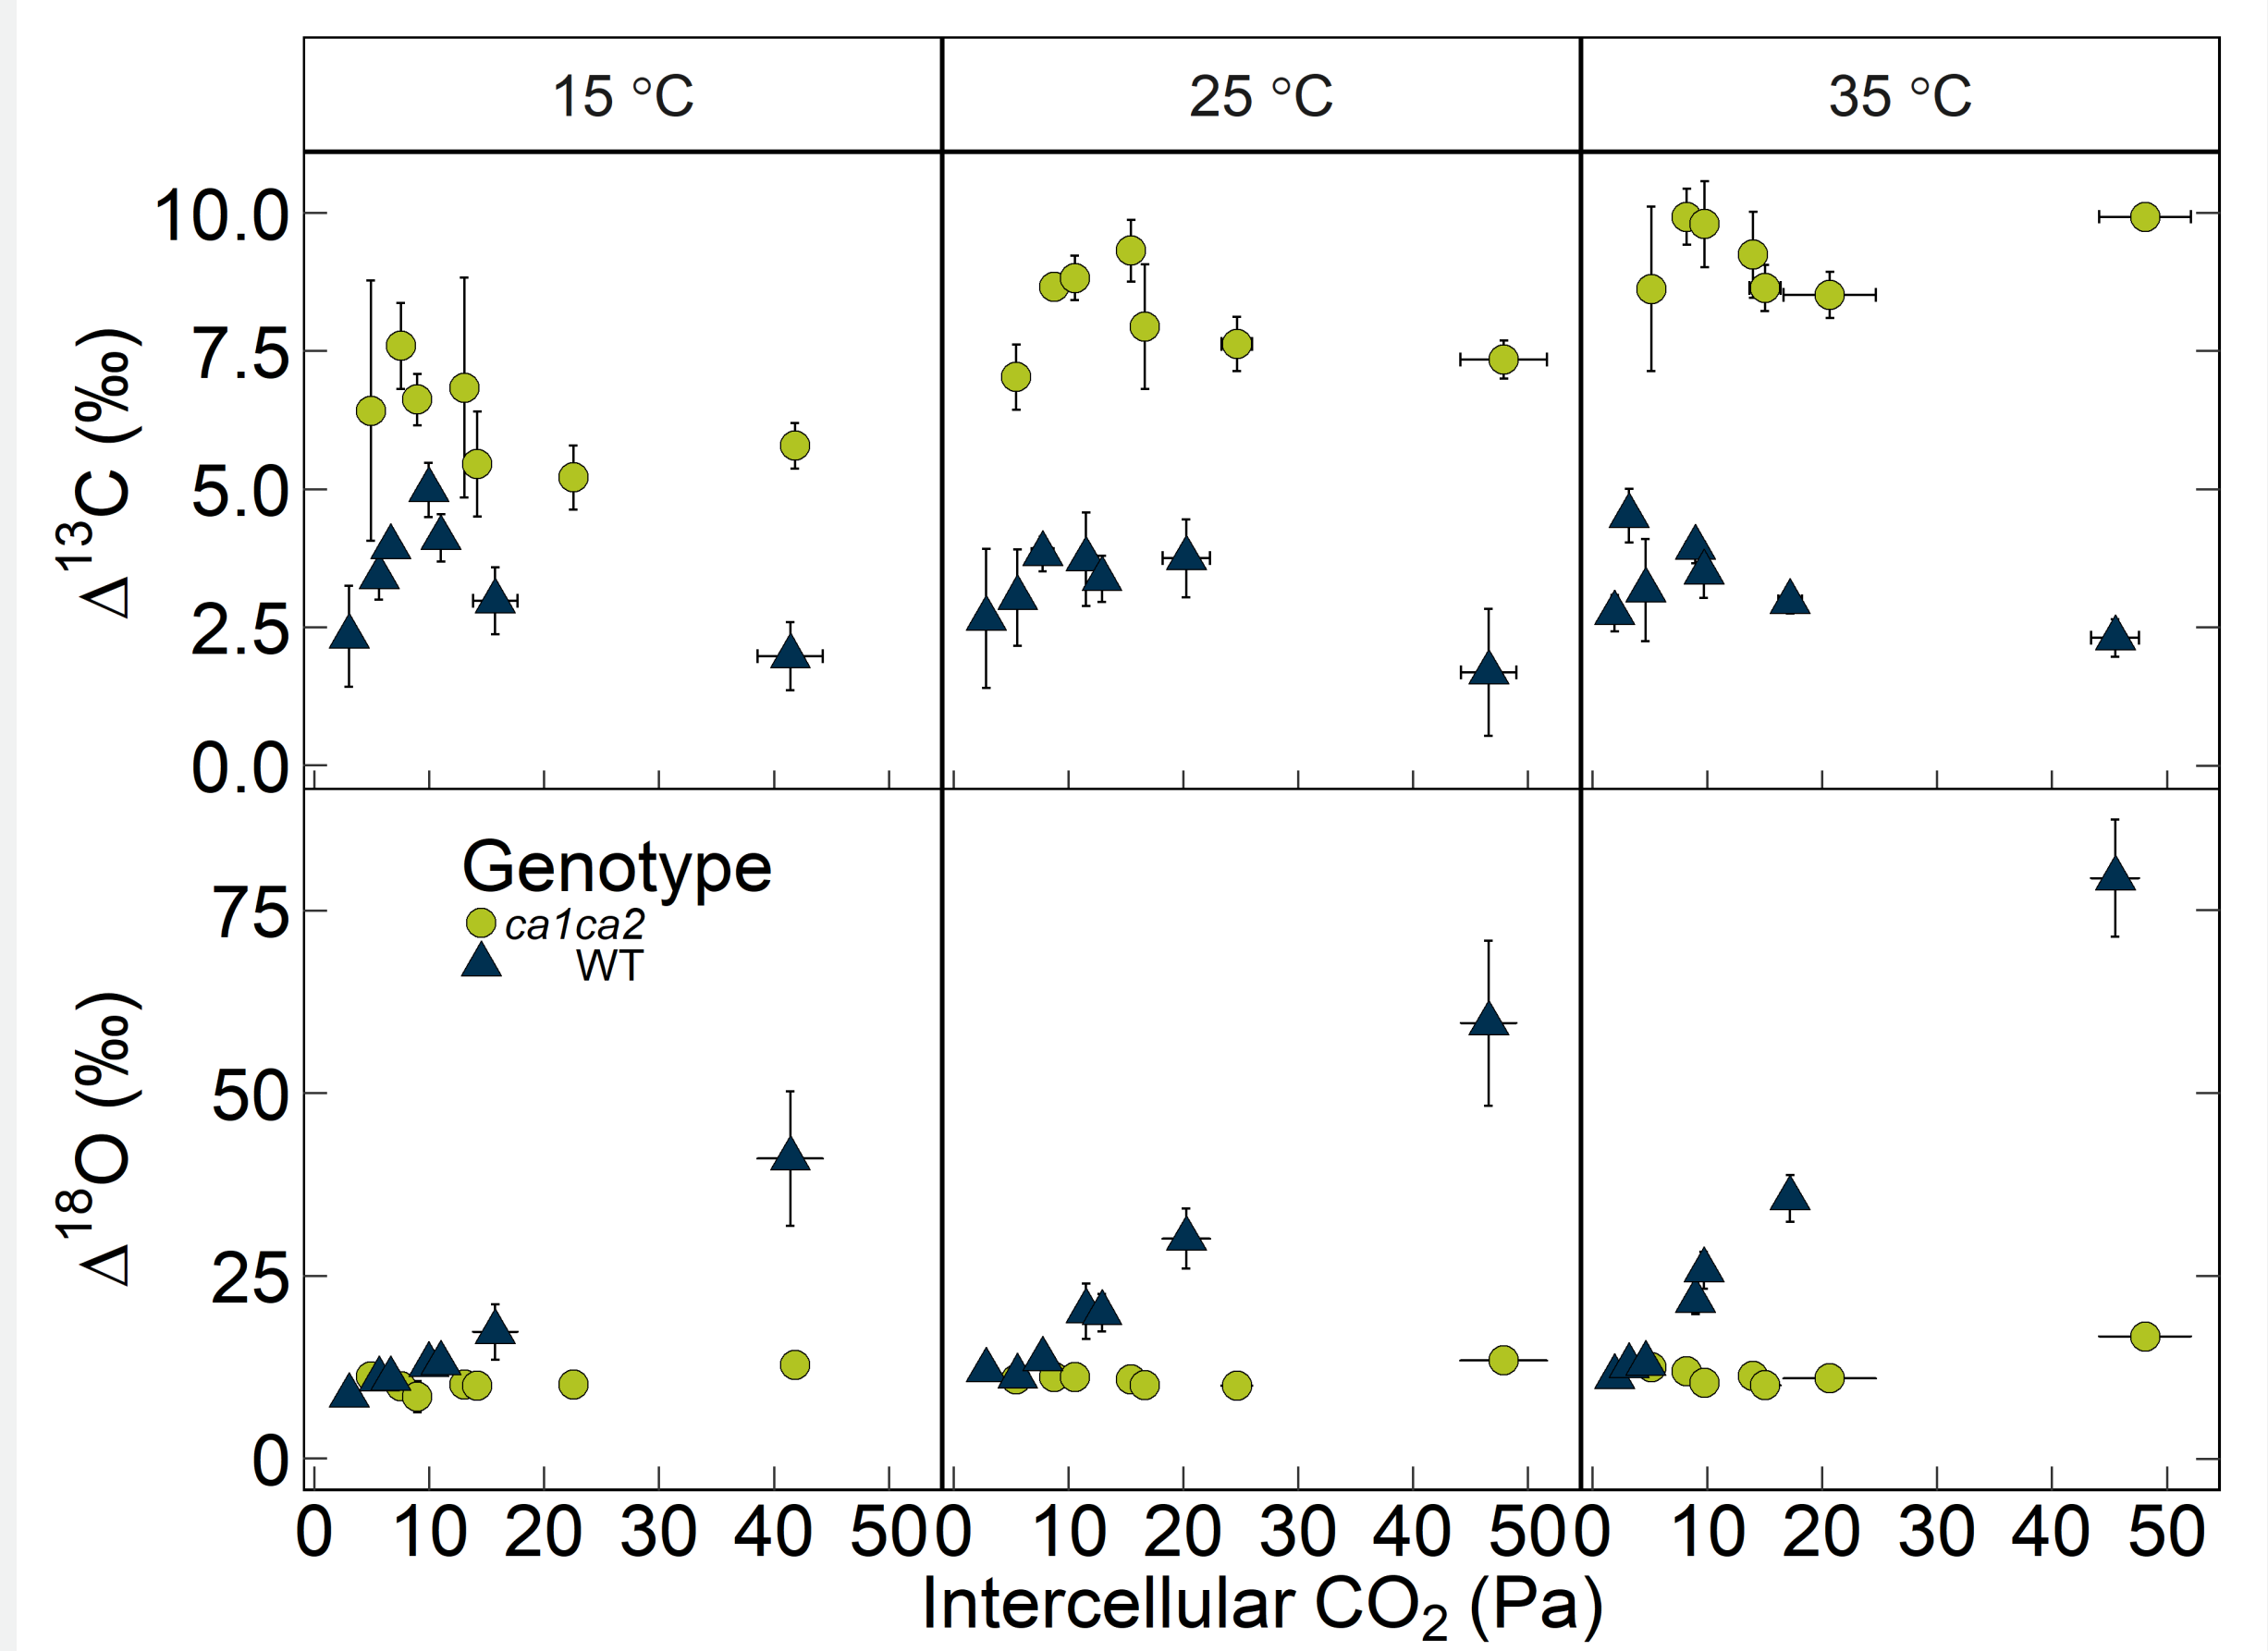

Figure 5: Gas exchange and online measurements of leaf Δ<sup>13</sup>CO<sub>2</sub> and Δ<sup>18</sup>O<sub>2</sub>.

- Differences in Δ<sup>13</sup>C suggest that lack of CA increases rates of PEPC activity to CO<sub>2</sub> hydration by CA and limits HCO<sub>3</sub><sup>-</sup> supply to PEPC
- Differences in Δ<sup>18</sup>O suggest that CO<sub>2</sub> and cytosolic H<sub>2</sub>O are not in isotopic equilibrium

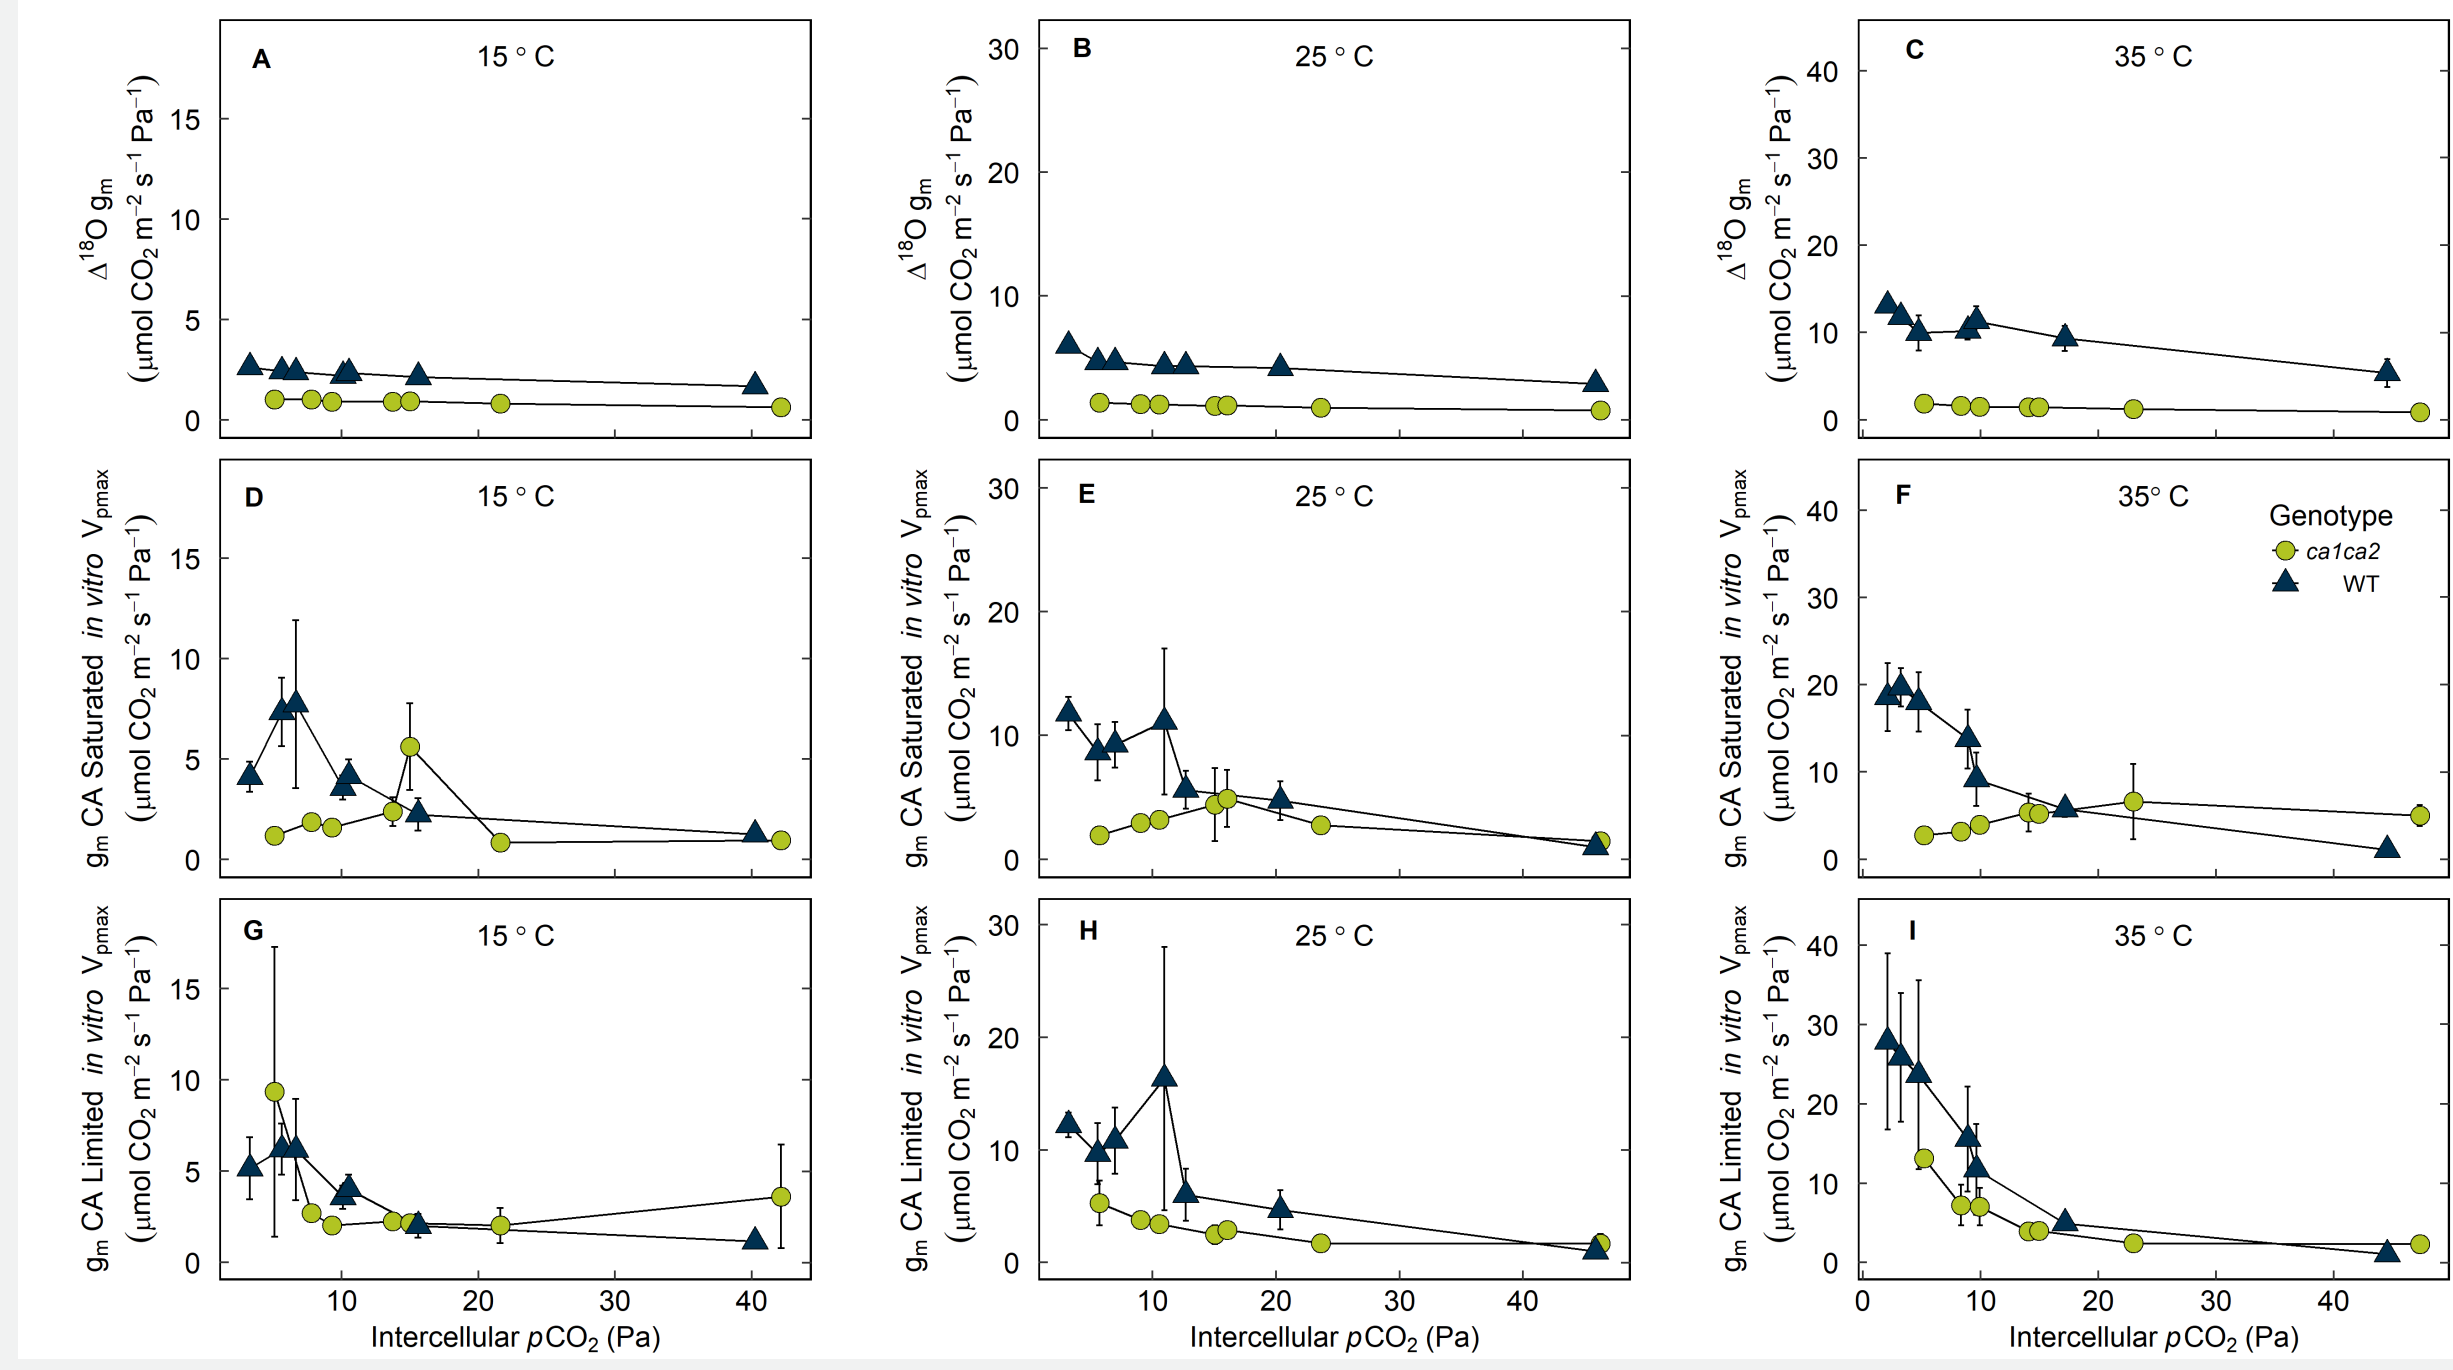

Figure 6: Mesophyll conductance measurements with increasing temperature and pCO<sub>2</sub> on *ca1ca2* and WT plants. Δ<sup>18</sup>O-g<sub>m</sub> (A-C), *in vitro* V<sub>pmax</sub> CA Saturated-g<sub>m</sub> (D-F), and *in vitro* V<sub>pmax</sub> CA Limited-g<sub>m</sub> (G-I)

- Δ<sup>18</sup>O-g<sub>m</sub> method is sensitive to CA activity and drastically underestimates g<sub>m</sub>
- CA exhibits little effect on calculated g<sub>m</sub> when modeled with *in vitro* enzyme data

## Conclusions

- CA limits C<sub>4</sub> photosynthesis more at higher temperatures by substrate limitation to PEPC
- CA is not a large component of mesophyll conductance in C<sub>4</sub> maize
- Methods to measure g<sub>m</sub> in C<sub>4</sub> plants should cautiously consider the effects of CA on HCO<sub>3</sub><sup>-</sup> availability
